Comparison of methods in the `metap` package

Michael Dewey

November 15, 2019

1 Introduction

1.1 What is this document for?

This document describes some methods for the meta–analysis of p–values (significance values) contained in the package `metap` and contains comments on the performance of the various algorithms under a small number of different scenarios with hints on the choice of method.

1.2 Notation

The k studies give rise to p–values, p_i, $i = 1, \ldots, k$. These are assumed to be independent. We shall also need the ordered p–values: $p_{[1]} \leq p_{[2]}, \ldots, \leq p_{[k]}$ and weights w_i, $i = 1, \ldots, k$. Logarithms are natural. A function for combining p–values is denoted g. The size of the test is α. We may also need k degrees of freedom, ν_i.

The methods are referred to by the name of the function in `metap`. Table 1 shows other descriptions of each method.

2 Theoretical results

There have been various attempts to clarify the problem and to discuss optimality of the methods. A detailed account was provided by Lipták (1958).

Birnbaum (1954) considered the property of admissibility. A method is admissible if when it rejects H_0 for a set of p_i it will also reject H_0 for P_i^* where

Function name	Description(s)	
	Eponym	
`invchisq`	Lancaster's method	Inverse chi square
`invt`		Inverse t
`logitp`		Logistic
`meanp`		
`meanz`		
`maximump`		
`minimump`	Tippett's method	
`sumlog`	Fisher's method	Chi square (2 df)
`sump`	Edgington's method	Uniform
`sumz`	Stouffer's method	Normal
`truncated`	Truncated Fisher	rank–truncated
`votep`		
`wilkinsonp`	Wilkinson's method	

Table 1: Methods considered in this document

$p_i^* \leq p_i$ for all i. He considered that Fisher's and Tippett's method were admissible. See also Owen (2009).

He also points out the problem is poorly specified. This may account for the number of methods available and their differing behaviour. The null hypothesis H_0 is well defined, that all p_i have a uniform distribution on the unit interval. There are two classes of alternative hypothesis

- H_A: all p_i have the same (unknown) non–uniform, non–increasing density,

- H_B: at least one p_i has an (unknown) non–uniform, non–increasing density.

If all the tests being combined come from what are basically replicates then H_A is appropriate whereas if they are of different kinds of test or different conditions then H_B is appropriate. Note that Birnbaum specifically considers the possibility that the tests being combined may be very different for instance some tests of means, some of variances, and so on.

3 The methods

3.1 Comparison scenarios

To provide a standard of comparison we shall use the following two situations. Some authors have also used the case of exactly two p_i.

What if all $p_i = p$? Perhaps surprisingly there are substantial differences here as we shall see when we look at each method. We shall describe how the returned value varies with p and k.

Cancellation When the collection of primary studies contains a number of values significant in both directions the methods can give very different results. If the intention of the synthesis is to examine a directional hypothesis one would want a method where these cancelled out. The decision between methods should be made on theoretical grounds of course. We shall use the following four values as our example.

```
> cancel <- c(0.001, 0.001, 0.999, 0.999)
```

3.2 Methods using transformation of the p–values

One class of methods relies on transforming the p–values first.

Function name	Definition	Critical value
`invchisq`	$\sum_{i=1}^{k} \chi^2_{\nu_i}(p_i)$	$\chi^2_{\sum \nu_i}(\alpha)$
`invt`	$\dfrac{\sum_{i=1}^{k} t_{\nu_i}(p_i)}{\sqrt{\sum_{i=1}^{k} \frac{\nu_i}{\nu_i - 2}}}$	$z(\alpha)$
`logitp`	$\dfrac{\sum_{i=1}^{k} \log \frac{p}{1-p}}{C}$ where $C = \sqrt{\frac{k\pi^2(5k+2)}{3(5k+4)}}$	t_{5k+4}
`meanz`	$\dfrac{\bar{z}}{s_{\bar{z}}}$ where $\bar{z} = \sum_{i=1}^{k} \frac{z(p_i)}{k}$ and $s_{\bar{z}} = \frac{s_z}{\sqrt{k}}$	$t_{k-1}(\alpha)$
`sumlog`	$\sum_{i=1}^{k} -2 \log p_i$	$\chi_{2k}(\alpha)$
`sumz`	$\dfrac{\sum_{i=1}^{k} z(p_i)}{\sqrt{k}}$	$z(\alpha)$

Table 2: Definitions of methods using transformation of the p values

3.2.1 The method of summation of logs, Fisher's method

See Table 2 for the definition. This works because $-2 \log p_i$ is a χ_2^2 and the sum of χ^2 is itself a χ^2 with degrees of freedom equal to the sum of the degrees of freedom of the individual χ^2. Of course the sum of the log of the p_i is also the log of the product of the p_i. Fisher's method (Fisher, 1925) is provided in `sumlog`. It would of course be possible to generalise this to use transformation to χ^2 with any other number of degrees of freedom rather than 2. Lancaster (1961) suggests that this is highly correlated with `sumlog`. Lancaster's method is provided in `invchisq`. In fact the resemblance to `sumlog` becomes less as the number of degrees of freedom increases.

As can be seen in Figure 1 when all the $p_i = p$ `sumlog` returns a value which decreases with k when $p < 0.32$, increases with k when $p > 0.37$, and in between increases with k and then decreases. Some detailed algebra provided in a post to https://stats.stackexchange.com/questions/243003 by Christoph Hanck suggests that the breakpoint is $e^{-1} = 0.3679$. Where the p_i are less than this then for a sufficiently large k (several hundred) the result will be significant and not if above that. Over the range of k we are plotting this bound is not yet closely approached.

Figure 1: Behaviour of the methods using transformed p values for k values of $p = p_i$

3.2.2 The method of summation of z values, Stouffer's method

The method of summation of z values is provided in `sumz` (Stouffer et al., 1949). See Table 2 for the definition. As can be seen in Figure 1 it returns a value for our $p_i = p$ example which decreases with k when p below 0.5

4

and increases above. There is also a closely related method using the mean of normals provided in `meanz` also defined in Table 2 which has very similar properties except that when all the p_i are equal it either gives 0 or 1 as can be seen in Figure 1.

A weighted version of Stouffer's method is available $\frac{\sum_{i=1}^{k} w_i z(p_i)}{\sqrt{\sum_{i=1}^{k} w_i^2}}$ where w_i are the weights. In the absence of effect sizes (in which case a method using effect sizes would be more appropriate anyway) best results are believed to be obtained with weights proportional to the square root of the sample sizes (Zaykin, 2011) following Lipták (1958).

3.2.3 The inverse t method

A closely related method is the inverse t method. See Table 2 for the definition. This method is provided in `invt`. As is clear from the definition this method tends to Stouffer's method as $\nu_i \to \infty$.

3.2.4 The method of summation of logits

See Table 2 for the definition. This method is provided in `logitp`. The constant C was arrived at by equating skewness and kurtosis with that of the t–distribution (Loughin, 2004). As can be seen in Figure 1 this method returns a value for our $p_i = p$ example which decreases with k when p below 0.5 and increases above.

3.2.5 Examples for methods using transformations of the p values

Function name	validity	cancel
logitp	3.95405066641324e-16	0.5
meanz	8.09658964578493e-12	0.5
sumlog	2.98981918888483e-16	0.000548861519997557
sumz	1.33915623099787e-16	0.5

Table 3: Examples of methods using transformation of the p values

Using the same example dataset which we have already plotted and our cancellation dataset we have the values in Table 3. As can be seen all the methods cancel except for `sumlog`. The agreement for the validity dataset is close. Lancaster's method and inverse t are not shown as they are both infinite families of possible methods.

3.3 Methods using untransformed p–values

Function name	Definition	Critical value
`meanp`	$\bar{p} = \frac{\sum_{i=1}^{k} p_i}{k}$ $z = (0.5 - \bar{p})\sqrt{12k}$	$z(\alpha)$
`minimump`	$p_{[1]}$	$1 - (1-\alpha)^{\frac{1}{k}}$
`maximump`	$p_{[k]}$	α^k
`wilkinsonp`	$p_{[r]}$	$\sum_{s=r}^{k} \binom{k}{s}\alpha^s(1-\alpha)^{k-s}$
`sump`	$\frac{(S)^k}{k!} - \binom{k-1}{1}\frac{(S-1)^k}{k!} + \binom{k-2}{2}\frac{(S-2)^k}{k!} - \ldots$ where $S = \sum_{i=1}^{k} p_i$	α

Table 4: Definitions of methods not using transformation of the p values, the series for `sump` continues until the term in in the numerator $(S - i)$ becomes negative

Figure 2: Behaviour of the methods using untransformed p values for k values of $p = p_i$

3.3.1 The method of minimum p, maximum p, and Wilkinson's method

The methods of minimum p (Tippett, 1931), maximum p and Wilkinson (Wilkinson, 1951) are defined in Table 4. Wilkinson's method depends on which value (the rth) of $p_{[i]}$ is selected. Wilkinson's method is provided in `wilkinsonp` and a convenience function `minimump` with its own `print` method is provided for the minimum p method $(r = 1)$. It is also possible

to use the method for the maximum p (that is $r = k$) and a convenience function `maximump` is provided for that purpose.

As can be seen in Figure 2 these methods return a value for our $p_i = p$ example which always increases with k which is true for `minimump` and which always decreases with k which is true for `maximump`

3.3.2 The method of summation of p–values, Edgington's method

Defined in Table 4 (Edgington, 1972a). This method is provided in `sump`. As can be seen in Figure 2 this method returns a value for our $p_i = p$ example which decreases with k when p below 0.5 and increases above.

Some authors use a simpler version, $\frac{(\sum p)^k}{k!}$, for instance Rosenthal (1978) in the text although compare his Table 4. This can be very conservative when $\sum p > 1$ There seems no particular need to use this method but it is returned by `sump` as the value of `conservativep` for use in checking published values.

Note also that there can be numerical problems for extreme values of S and in that case recourse might be made to `sumz` or `logitp` which have similar properties.

3.3.3 The mean p method

Defined in Table 4. Although this method is attributed to Edgington (Edgington, 1972b) when the phrase Edgington's method is used it refers to the method of summation of p–values described above in Section 3.3.2. As can be seen in Figure 2 this method returns a value for our $p_i = p$ example which decreases with k when p below 0.5 and increases above.

3.3.4 Examples for methods using untransformed p–values

Using the same example dataset which we have already plotted and our cancellation dataset we have the values in Table 5. As can be seen `meanp` and `sump` cancel but the other two do not. Agreement here is not so good especially for the maximump method. Wilkinson's method not shown as it depends on the value of r.

Function name	validity	cancel
minimump	5.99982900307796e-05	0.003994003999
maximump	0.00232656906767947	0.996005996001
meanp	2.40510184300166e-09	0.5
sump	2.3561224666017e-11	0.5

Table 5: Examples for methods using the untransformed p values

3.4 Other methods

3.4.1 The method of vote–counting

A simple way of looking at the problem is vote counting. Strictly speaking this is not a method which combines p–values in the same sense as the other method. If most of the studies have produced results in favour of the alternative hypothesis irrespective of whether any of them is individually significant then that might be regarded as evidence for that alternative. The numbers for and against may be compared with what would be expected under the null using the binomial distribution. A variation on this would allow for a neutral zone of studies which are considered neither for nor against. For instance one might only count studies which have reached some conventional level of statistical significance in the two different directions.

This method returns a value for our $p_i = p$ example which is 1 for p values above 0.5 and otherwise invariant with p but decreases with k. This method does cancel significant values in both directions.

Function name	validity	cancel
votep	0.000201225280761719	0.6875

Table 6: Examples for vote counting

3.4.2 Methods not using all p–values

If there is a hypothesis that the signal will be concentrated in only a few p–values then alternative methods are available in `truncated`. This is a wrapper to two packages available on CRAN: `TFisher` which provides the truncated Fisher method (Zaykin et al., 2007; Zhang et al., 2018) and `mutoss` which provides the rank–truncated Fisher method (Dudbridge and Koeleman, 2003). Note that Table 7 only shows results for the validity data–set

as, since the methods explicitly only consider results in one direction the cancellation issue does not arise.

Function name	truncated at $p = 0.5$	truncated at rank = 5
`truncated`	4.44089209850063e-16	8.72324438661104e-09

Table 7: Examples for truncated using the validity data–set

4   Loughin's recommendations

In his simulation study Loughin (2004) carried out extensive comparisons. He bases his recommendations on criteria of structure and the arrangement of evidence against H_0.

Under structure he considers three cases with the following recommendations: emphasis on small p–values (`sumlog` and `minimump`), emphasis on large p–values (`maximump` and `sump`), and equal emphasis (`logitp` and `sumz`).

Under arrangement of evidence he considers where this is concentrated. His recommendations are summarised in Table 8 but note that he did not consider all of the methods provided in this package.

Equal in all tests	$k < 10$ `sump`, `maximump`
	Any k `sumz`, `logitp`
Some in all tests	$k < 10$ `sump`, `maximump`
	Any k `sumz`, `logitp`
In majority of tests	`sumz`, `logitp`
In minority of tests	Moderate or strong evidence `sumlog`
	Any power `sumz`, `logitp`
In one test only	Strong total evidence `minimup`
	Moderate total evidence `sumlog`
	Weak total evidence `sumz`, `logitp`

Table 8: Loughin's recommendations for method choice
